DATA 301: Data Cleaning

Data Cleaning - Outline

- Why
- Missing Values
- Duplicates
- Strings
- Categorical data
- Numerical Data
- Dates

Why

Data is usually messy.

You can minimize some problems

 For surveys, prefer comboboxes populated with a curated list rather than free form text field

Some you cannot

- external datasets (like your first project)
- free form text (like a collection of movie reviews)
- Missing and duplicate values
- Sensor data (outliers, missing values)

Either way it has to be cleaned

Remove duplicates
Handle missing data
Process strings

Many machine learning algorithms require data to be in numerical format(linear regression, neural networks, clustering), but not all (random forest). If you are using data for input to an algorithm that requires numerical data, then there are some additional steps.

Process Categorical data Normalize Data Process dates (if needed) Reduce dimensionality

Remove duplicates
Handle missing data
Process strings

Did much of this when introducing project 1

Many machine learning algorithms require data to be in numerical format(linear regression, neural networks, clustering), but not all (random forest). If you are using data for input to an algorithm that requires numerical data, then there are some additional steps.

Process Categorical data Normalize Data Process dates (if needed) Reduce dimensionality

Remove duplicates
Handle missing data
Process strings

Todays topics

Many machine learning algorithms require data to be in numerical format(linear regression, neural networks, clustering), but not all (random forest). If you are using data for input to an algorithm that requires numerical data, then there are some additional steps.

Process Categorical data Normalize Data Process dates (if needed) Reduce dimensionality

Todays topics

Many machine learning algorithms require data to be in numerical format(linear regression, neural networks, clustering), but not all (random forest). If you are using data for input to an algorithm that requires numerical data, then there are some additional steps.

Process Categorical data Process Numerical data Normalize Data Process dates (if needed) Reduce dimensionality

This is not a complete list of steps

First see if there are any

1 df.duplicated().sum()

First see if there are any

```
1 df.duplicated().sum()
```

If so then verify them visually

```
1 df[df.duplicated()].sort_values(by='name')
```

First see if there are any

```
1 df.duplicated().sum()
```

If so then verify them visually

```
1 df[df.duplicated()].sort_values(by='name')
```

If everything looks fine, get rid of them

```
1 df.drop_duplicates(inplace=True)
```

First see if there are any

```
1 df.duplicated().sum()
```

If so then verify them visually

```
1 df[df.duplicated()].sort_values(by='name')
```

If everything looks fine, get rid of them

```
1 df.drop_duplicates(inplace=True)
```

But there could be extenuating circumstances; What if a duplicate row is missing some data?

First see if there are any

```
1 df.duplicated().sum()
```

If so then verify them visually

```
1 df[df.duplicated()].sort_values(by='name')
```

If everything looks fine, get rid of them

```
1 df.drop_duplicates(inplace=True)
```

But there could be extenuating circumstances; What if duplicate is missing some data?

Go to 31_cleaning_missing_and_duplicate_data.ipynb

Categorical data

Categorical data can be subdivided into 2 types
Ordinal data— data that has an order, can be sorted

- ex. t-shirt size (small<medium<large)
- The average of a small and large <u>is</u> medium

Nominal data – data that has no order

- ex. t-shirt color (Red, Blue, Green) one is not greater than another
- The average of Red and Green is not Blue

Categorical data

Categorical data can be subdivided into 2 types Ordinal data— data that has an order, can be sorted

- ex. t-shirt size (small<medium<large)
- The average of a small and large is medium

Nominal data – data that has no order

- ex. t-shirt color (Red, Blue, Green) one is not greater than another
- The average of Red and Green is not Blue

Both types need to be encoded numerically in order to be used by many ML models. But their encoding techniques differ.

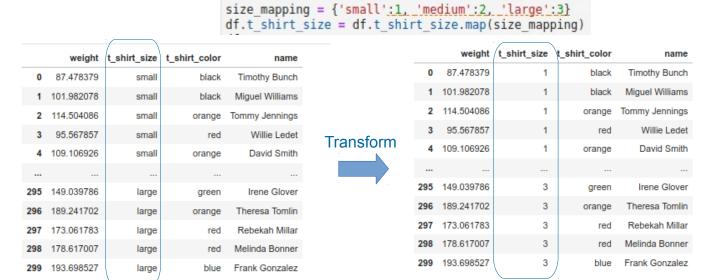

Ordinal data

300 rows × 4 columns

Ordinal data- data that has an order, can be sorted

ex. t-shirt size (small<medium<large)

Since it has an order, just convert it to a number

300 rows × 4 columns

Nominal data

Does not have an order so cannot convert a nominal categorical variable to a number in the same way that you do a Ordinal one because you would then imply an order.

T-shirt color is nominal ts_colors = ['green', 'blue', 'orange', 'red', 'black']

How to convert t-shirt color to a number without an order?

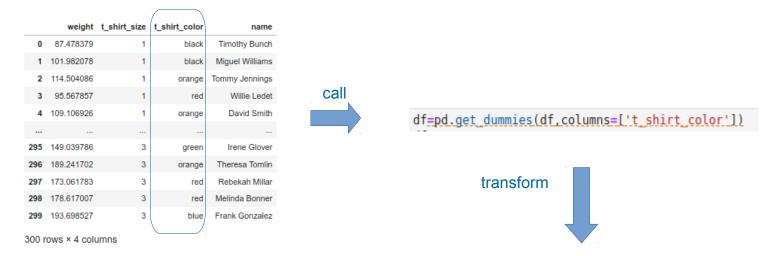

Nominal data

Does not have an order so cannot convert a nominal categorical variable to a number in the same way that you do a Ordinal one because you would then imply an order.

T-shirt color is nominal ts_colors = ['green', 'blue', 'orange', 'red', 'black']

How to convert t-shirt color to a number without an order? Use something called One Hot Encoding. You create 1 column for each unique nominal value.

Nominal data – One Hot Encode t shirt color

Notice that there is now 1 column per color. Only 1 of those columns will ever be 1 at a time, the rest will be 0's

	weight	t_shirt_size	name	t_shirt_color_black	t_shirt_color_blue	t_shirt_color_green	t_shirt_color_orange	t_shirt_color_red
